UPPER TAILS FOR INTERSECTION LOCAL TIMES OF RANDOM WALKS IN SUPERCRITICAL DIMENSIONS

Xia Chen and Peter Mörters

University of Tennessee and University of Bath

ABSTRACT. We determine the precise asymptotics of the logarithmic upper tail probability of the total intersection local time of p independent random walks in $\mathbb{Z}^d$ under the assumption $p(d-2) > d$. Our approach allows a direct treatment of the infinite time horizon.

1. INTRODUCTION AND MAIN RESULT

1.1 Motivation

Quantities measuring the amount of self-intersection of a random walk, or of mutual intersection of several independent random walks have been studied intensively for more than twenty years, see *e.g.* [DV79, LG86, La91, MR97, HK01, Ch04]. This research is often motivated by the rôle these quantities play in quantum field theory, see *e.g.* [FFS92], in our understanding of self-avoiding walks and polymer models, see *e.g.* [MS93], or in the analysis of stochastic processes in random environments, see *e.g.* [HKM06, GKS07, AC07, FMW08]. In the latter models dependence between a moving particle and a random environment frequently comes from the particle's ability to revisit sites with a (in some sense) attractive environment, and therefore measures of self-intersection quantify the degree of dependence between movement and environment. Typically, in high dimensions this dependence gets weaker, as the movements become more transient and self-intersections less likely.

In their influential paper [KM94], Khanin, Mazel, Shlosman and Sinai make the surprising observation that even in high dimensions the random variables counting the total number of intersections of two independent simple random walks have subexponential tails at infinity. They argue that this observation is intimately related to the fact that a random walk in random potential has subdiffusive behaviour in all dimensions. Similar observations were made at around the same time by Sznitman in a continuous setting, see [Sz93]. In their analysis of intersection measures of high-dimensional random walks, Khanin *et al.* obtain estimates for the tails at infinity, but there are still significant gaps between the given upper and lower bounds, which despite considerable effort have not been resolved in the past ten years. In this paper we make a contribution to the closure of these gaps.

To be precise, let $(X^{(1)}(n) : n \in \mathbb{N}), \ldots, (X^{(p)}(n) : n \in \mathbb{N})$ be p independent identically distributed random walks taking values in $\mathbb{Z}^d$. The number of intersections of the walks can be measured in two natural ways: The *intersection local time*,

$$I := \sum_{i_1=1}^{\infty} \cdots \sum_{i_p=1}^{\infty} \mathbb{1}\{X^{(1)}(i_1) = \cdots = X^{(p)}(i_p)\},$$

counts the *times* when the paths intersect, whereas the *intersection of the ranges*,

$$J := \sum_{x \in \mathbb{Z}^d} \mathbb{1}\{X^{(1)}(i_1) = \cdots = X^{(p)}(i_p) = x \text{ for some } (i_1, \ldots, i_p)\},$$

counts the *sites* where the paths intersect. Obviously, we always have $J \leq I$.

Moreover, under suitable conditions on the random walk, it is well known that

$$\mathbb{P}\{I < \infty\} = \mathbb{P}\{J < \infty\} = \begin{cases} 1 & \text{if } p(d-2) > d, \\ 0 & \text{otherwise.} \end{cases}$$

The lower bounds here are easy and hold for all symmetric, aperiodic random walks with finite variance, while the upper bounds hold for simple, symmetric walks by a celebrated result of Dvoretzky and Erdős [DE51]. We assume throughout this paper that $p(d-2) > d$, i.e. we are assuming that we are in *supercritical* dimensions. Then, in the case of simple, symmetric random walks, Khanin *et al.* show in [KM94] that there exist constants $c_1, c_2 > 0$ such that, for all a large enough,

$$\exp\big\{ - c_1 a^{\frac{1}{p}} \big\} \leq \mathbb{P}\{I > a\} \leq \exp\big\{ - c_2 a^{\frac{1}{p}} \big\}.$$

Interestingly, the upper tails of J are substantially lighter. Khanin *et al.* show that, for all $\varepsilon > 0$ and all sufficiently large a,

$$\exp\big\{ - a^{\frac{d-2}{d} + \varepsilon} \big\} \leq \mathbb{P}\{J > a\} \leq \exp\big\{ - a^{\frac{d-2}{d} - \varepsilon} \big\}.$$

The challenging question lies in understanding the difference of these behaviours, providing sharp estimates for the tails, and understanding the underlying 'optimal strategies'.

The most important recent progress on this problem was made by van den Berg, Bolthausen and den Hollander [BBH04] for the spatially and temporally continuous analogue of J: Let $W_1^\varepsilon(t)$ and $W_2^\varepsilon(t)$ be the ε-neighbourhoods of two independent Brownian paths starting at the origin and running for t time units, and use $|\cdot|$ to denote Lebesgue measure. They show that, for $d \geq 3$,

$$\lim_{t\uparrow\infty} \frac{1}{t^{(d-2)/d}} \log \mathbb{P}\big\{ \big| W_1^\varepsilon(\theta t) \cap W_2^\varepsilon(\theta t) \big| \geq t \big\} = -I_d^\varepsilon(\theta),$$

and, if $d \geq 5$, there exists a critical θ^* such that $I_d^\varepsilon(\theta) = I_d^\varepsilon(\theta^*)$ for all $\theta \geq \theta^*$. This strongly suggests that, in the supercritical case $d \geq 5$,

$$\lim_{t\uparrow\infty} \frac{1}{t^{(d-2)/d}} \log \mathbb{P}\big\{ \big| W_1^\varepsilon(\infty) \cap W_2^\varepsilon(\infty) \big| \geq t \big\} = -I_d^\varepsilon(\theta^*),$$

but the techniques of [BBH04] are strongly reliant on Donsker-Varadhan large deviation theory and, mostly for this reason, do not allow the treatment of *infinite* times. Therefore this problem, like its discrete counterpart, remains open for the time being.

In the present paper we focus on the intersection local time I, working directly in the discrete setting. We provide sharp estimates for the tail behaviour of I, in other words we identify the limit

$$\lim_{a\uparrow\infty} \frac{1}{a^{1/p}} \log \mathbb{P}\big\{ I > a \big\},$$

which is given in terms of a natural associated variational problem. The important progress here lies in the fact that our method avoids the use of Donsker-Varadhan large deviation theory and instead allows a direct treatment of *infinite* times. The proofs provide new insight into the optimal strategies leading to the event $\{I > a\}$. An interpretation of the results is that the bulk of the intersections contributing to large values of I are attained in a *bounded* subset of $\mathbb{Z}^d$. Naturally, this strategy does not lead to large values of J, which therefore have to be obtained by a different, more expensive, strategy.

1.2 Statement of the main results

1.2.1 Intersection local times for discrete time random walks. Let $(X^{(1)}(n) : n \in \mathbb{N}), \ldots, (X^{(p)}(n) : n \in \mathbb{N})$ be p independent identically distributed random walks started at time $n = 0$ in the origin and taking values on the lattice $\mathbb{Z}^d$. Suppose that the walks are aperiodic, have symmetric increments and finite variance, and that d is sufficiently large to satisfy $p(d-2) > d$, i.e. we are in supercritical dimensions.

Let $\mathbb{G}$ be *Green's function* associated to the random walk, defined by

$$\mathbb{G}(x) := \sum_{n=1}^{\infty} \mathbb{P}\{X^{(1)}(n) = x\}.$$

Note that we are following the (slightly unusual) convention of not summing over the time $n = 0$, which only influences the value $\mathbb{G}(0)$. We first state integrability and boundedness of some operators associated with Green's function.

Lemma 1. *Let $q > 1$ be the conjugate of p defined by $p^{-1} + q^{-1} = 1$. For every nonnegative $h \in L^q(\mathbb{Z}^d)$ a bounded, symmetric operator $\mathfrak{A}_h \colon L^2(\mathbb{Z}^d) \to L^2(\mathbb{Z}^d)$ is defined by*

$$\mathfrak{A}_h g(x) = \sqrt{e^{h(x)} - 1} \sum_{y \in \mathbb{Z}^d} \mathbb{G}(x - y) g(y) \sqrt{e^{h(y)} - 1}.$$

Moreover, we have $\mathbb{G} \in L^p(\mathbb{Z}^d)$ and for the spectral radius, or operator norm,

$$\|\mathfrak{A}_h\| := \sup \left\{ |\langle g, \mathfrak{A}_h g \rangle| : \|g\|_2 = 1 \right\} = \sup \left\{ \langle g, \mathfrak{A}_h g \rangle : g \geq 0, \|g\|_2 = 1 \right\} \tag{1}$$

of the operator $\mathfrak{A}_h$ we have the inequality

$$\|\mathfrak{A}_h\| \leq \|\mathbb{G}\|_p \left(e^{\|h\|_q} - 1 \right). \tag{2}$$

Note that the alternative description of the spectral radii of $\mathfrak{A}_h$, for nonnegative $h \in L^q(\mathbb{Z}^d)$, on the right hand side of (1) holds trivially because Green's function is nonnegative. The next theorem, which is our main result, shows that this family of spectral radii can be used to describe the upper tail constant of the intersection local time. Its proof will be given in Section 2.

Theorem 2. *The upper tail behaviour of the intersection local time I is given as*

$$\lim_{a \uparrow \infty} \frac{1}{a^{1/p}} \log \mathbb{P}\{I > a\} = -p \inf \left\{ \|h\|_q : h \geq 0 \text{ with } \|\mathfrak{A}_h\| \geq 1 \right\}, \tag{3}$$

and the right hand side is negative and finite.

Remark 1.

(*a*) Heuristically, the optimal strategy for the random walks to realise the event $\{I > a\}$ is to spend each about $a^{1/p}$ time units in all points of a finite domain $A \subset \mathbb{Z}^d$, which is not growing with a. This leads to a typical intersection local time $I \approx a$ on this domain alone. As $a \uparrow \infty$ the intersection sites do not spread out in space when the random walks are conditioned on $\{I > a\}$, hence this strategy makes I large without making J large. This explains the fundamental difference between these two quantities in supercritical dimensions.

(*b*) Our proof provides the following evidence for this behaviour: Suppose $A \subset \mathbb{Z}^d$ is a finite set and

$$I(A) := \sum_{i_1=1}^{\infty} \cdots \sum_{i_p=1}^{\infty} \mathbb{1}\{X^{(1)}(i_1) = \cdots = X^{(p)}(i_p) \in A\},$$

the number of intersections in the set A. Then we show, as a by-product of the proof of Theorem 2, that

$$\lim_{a\uparrow\infty}\frac{1}{a^{1/p}}\,\log\mathbb{P}\{I(A)>a\}=-p\inf\left\{\|h\|_q\;:\;h\geq 0,\ \mathrm{supp}\,h\subset A\ \text{with}\ \|\mathfrak{A}_h\|\geq 1\right\}.\qquad(4)$$

It is easy to see that, as $A\uparrow\mathbb{Z}^d$, the right hand side in (4) converges to the right hand side in (3), and thus for large A the tails of $I(A)$ come arbitrarily close to those of I.

(c) A further interesting feature of our result is that the rate of decay of $\mathbb{P}\{I(A)>a\}$ is invariant under spatial shifts of A, in other words, at the given scale the random walks show no preference for locating their intersections near their starting point. This fact causes considerable difficulty in the proof of the upper bound, as the rate of $\mathbb{P}\{I(A^c)>a\}$ does not increase when A is getting large so that, loosely speaking, the problem is *not exponentially tight*. The technique to get around this problem is one of the main technical innovations in this paper.

Remark 2. From (2) we easily obtain an upper bound for the constant in (3), namely

$$-p\inf\left\{\|h\|_q\;:\;h\geq 0\ \text{with}\ \|\mathfrak{A}_h\|\geq 1\right\}\leq -p\log\left(1+\|\mathbb{G}\|_p^{-1}\right).$$

For a lower bound, we define the *potential operator*

$$\mathfrak{G}f(x):=\sum_{y\in\mathbb{Z}^d}\mathbb{G}(x-y)f(y),$$

and note that, as $\mathbb{G}\in L^p(\mathbb{Z}^d)$, this defines a bounded, symmetric operator

$$\mathfrak{G}\colon L^{\frac{2p}{2p-1}}(\mathbb{Z}^d)\longrightarrow L^{2p}(\mathbb{Z}^d)\,.$$

We thus get, using $e^h-1\geq h$ for $h\geq 0$, that

$$-p\inf\left\{\|h\|_q\;:h\geq 0,\ \sup_{\|g\|_2=1}\langle g,\mathfrak{A}_h g\rangle\geq 1\right\}$$

$$\geq -p\inf\left\{b\;:\;\sup_{\substack{\|g\|_2=1\\\|h\|_q=1}}\left\langle\sqrt{h}g,\mathfrak{G}\sqrt{h}g\right\rangle\geq 1/b\right\}$$

$$=-p/\sup\left\{\langle f^{2p-1},\mathfrak{G}f^{2p-1}\rangle\;:\;\|f\|_{2p}=1\right\}.$$

Neither of these bounds are sharp.

1.2.2 Intersection local times for continuous time random walks. It would be desirable to bring the variational formula on the right hand side of (3) into a form naturally interpretable as a competition between a probabilistic cost and benefit factor, and interpret the optimiser in terms of the optimal strategy of the walks. However, the present formula cannot be easily transformed to such a form, an artefact which we believe is due to the discrete time structure of the random walk.

We therefore provide a more transparent result for *continuous time random walk* for comparison. Let

$$(X^{(1)}(t)\;:\;t\geq 0),\ldots,(X^{(p)}(t)\;:\;t\geq 0)$$

be independent, identically distributed continuous time random walks and let A be their generator, defined by

$$\mathsf{A}f(x)=\lim_{t\downarrow 0}\frac{\mathbb{E}_x f(X_t^{(1)})-f(x)}{t}\,.$$

We assume that the random walks are aperiodic, and symmetric with finite variance. Then A is a nonpositive definite, symmetric operator. Based on Green's function

$$\mathsf{G}(x):=\int_0^\infty\mathbb{P}\{X(t)=x\}\,dt\,,$$

we define the potential operator $\mathfrak{G}$ as in the discrete time case, see Remark 2. Under our standing assumption of supercriticality, $d(p-2) > d$, it is easy to see that $\mathsf{G} \in L^p(\mathbb{Z}^d)$, and again that the potential operator is a bounded operator

$$\mathfrak{G} \colon L^{\frac{2p}{2p-1}}(\mathbb{Z}^d) \longrightarrow L^{2p}(\mathbb{Z}^d).$$

We define the *intersection local time* as

$$\tilde{I} := \int_0^\infty dt_1 \cdots \int_0^\infty dt_p \ \mathbb{1}\{X^{(1)}(t_1) = \cdots = X^{(p)}(t_p)\},$$

which is finite in the supercritical regime. As before, we ask for its upper tail behaviour.

Theorem 3. *The upper tail behaviour of the intersection local time $\tilde{I}$ is given as*

$$\lim_{a \uparrow \infty} \frac{1}{a^{1/p}} \log \mathbb{P}\{\tilde{I} > a\} = -p/\sup \left\{ \langle f^{2p-1}, \mathfrak{G} f^{2p-1} \rangle \ : \ \|f\|_{2p} = 1 \right\}, \tag{5}$$

where the right hand side is negative and finite.

Remark 3. Under some additional conditions, the formula on the right can be reformulated in an appealing way. Denote the supremum on the right hand side of (5) by ϱ. Given $\epsilon > 0$ choose $f \geq 0$ such that $\|f\|_{2p} = 1$ and $\langle f^{2p-1}, \mathfrak{G} f^{2p-1} \rangle \geq \varrho - \epsilon$. Then one can use that $-\mathsf{A} \circ \mathfrak{G} = \mathrm{id}$ and the fact that, by Hölder's inequality,

$$\|\mathfrak{G} f^{2p-1}\|_{2p} \geq \|f\|_{2p}^{-\frac{2p}{2p-1}} \left\langle f^{2p-1}, \mathfrak{G} f^{2p-1} \right\rangle \geq \varrho - \epsilon,$$

to obtain that

$$\varrho \geq \langle \mathfrak{G} f^{2p-1}, f^{2p-1} \rangle = \langle \mathfrak{G} f^{2p-1}, -\mathsf{A}\mathfrak{G} f^{2p-1} \rangle = (\varrho - \epsilon)^2 \left\langle \frac{\mathfrak{G} f^{2p-1}}{\varrho - \epsilon}, -\mathsf{A}\frac{\mathfrak{G} f^{2p-1}}{\varrho - \epsilon} \right\rangle$$

$$\geq (\varrho - \epsilon)^2 \inf \left\{ \langle g, -\mathsf{A}g \rangle \ : \ \|g\|_{2p} = 1 \right\},$$

whence, for $\epsilon \downarrow 0$, we get

$$\frac{1}{\varrho} \geq \inf \left\{ \langle g, -\mathsf{A}g \rangle \ : \ \|g\|_{2p} = 1 \right\}.$$

For the converse inequality, we assume that the generator A is such that there exists a positive minimiser g for the variational problem on the right hand side[1]. A simple perturbation calculation then yields the Euler-Lagrange equation $-\rho \mathsf{A}g = g^{2p-1}$, where $1/\rho$ denotes the minimum. Together with $-\mathsf{A} \circ \mathfrak{G} = \mathrm{id}$, this implies that, for some u with $\mathsf{A}u = 0$, we have $\rho g = \mathfrak{G} g^{2p-1} + u$. Note that u is vanishing at infinity and hence, assuming that A allows a maximum principle, we infer that $u = 0$. Therefore,

$$\frac{1}{\rho} = \langle g, -\mathsf{A}g \rangle = \frac{1}{\rho^2} \langle \mathfrak{G} g^{2p-1}, g^{2p-1} \rangle \leq \frac{\varrho}{\rho^2}.$$

Hence we obtain that the right hand side in (5) equals

$$-p \inf \left\{ \left\| \sqrt{-\mathsf{A}} g \right\|_2^2 \ : \ \|g\|_{2p} = 1 \right\}.$$

In this form, the constant has a natural interpretation: At least heuristically, the optimal strategy for each random walk is to build up a local time field

$$\ell^{(j)}(x) := \int_0^\infty \mathbb{1}\{X^{(j)}(t) = x\} \, dt \approx a^{1/p} g^2(x) \qquad \text{for all } j \in \{1, \ldots, p\},$$

which implies

$$\tilde{I} = \sum_{x \in \mathbb{Z}^d} \prod_{j=1}^p \ell^{(j)}(x) \approx \sum_{x \in \mathbb{Z}^d} \prod_{j=1}^p a^{1/p} g^2(x) = a.$$

---

[1]This assumption is generally nontrivial to verify, even for explicitly given A.

The probability of a random walk achieving such a local time is

$$\approx \exp\big\{-a^{1/p}\,\big\|\sqrt{-\mathsf{A}}g\big\|_2^2\big\},$$

which is reminiscent of the rate functions in Donsker-Varadhan theory.

Remark 4. The proof of Theorem 3 follows a similar strategy as in the discrete time case but, thanks to the absence of some combinatorial difficulties arising from the discrete time structure, it is considerably easier. Following the arguments analogous to Theorem 2 gives

$$\lim_{a\uparrow\infty}\frac{1}{a^{1/p}}\log\mathbb{P}\big\{\tilde{I}>a\big\}=-p\inf\big\{\|h\|_q\,:\,h\geq 0 \text{ with } \|\mathfrak{B}_h\|\geq 1\big\},$$

where the operator $\mathfrak{B}_h\colon L^2(\mathbb{Z}^d)\to L^2(\mathbb{Z}^d)$ is defined by

$$\mathfrak{B}_h g(x)=\sqrt{h(x)}\sum_{y\in\mathbb{Z}^d}\mathsf{G}(x-y)g(y)\sqrt{h(y)}\,.$$

Then one can observe that

$$\inf\big\{\|h\|_q\,:\,h\geq 0,\ \sup_{\|g\|_2=1}\langle g,\mathfrak{B}_h g\rangle\geq 1\big\}=\inf\big\{b\,:\,\sup_{\substack{\|g\|_2=1\\\|h\|_q=1}}\big\langle\sqrt{hg},\mathfrak{G}\sqrt{hg}\big\rangle\geq 1/b\big\}$$

$$=1/\sup\big\{\langle f^{2p-1},\mathfrak{G}f^{2p-1}\rangle\,:\,\|f\|_{2p}=1\big\}\,.$$

2. RANDOM WALKS IN DISCRETE TIME: PROOF OF THEOREM 2.

In Section 2.1 we provide the proof of Lemma 1. The proof of Theorem 2 is divided into *six* steps, presented in Sections 2.2 to 2.7 below. We now give a brief overview over these steps and the main techniques of the proof.

By Lemma 2.3 in [KM02] we have, for any nonnegative random variable X,

$$\lim_{k\uparrow\infty}\frac{1}{k}\log\mathbb{E}\Big[\frac{X^k}{(k!)^p}\Big]=-\kappa\quad\Longleftrightarrow\quad\lim_{a\uparrow\infty}\frac{1}{a^{1/p}}\log\mathbb{P}\{X>a\}=-pe^{\kappa/p}\,. \tag{6}$$

Moreover, it is elementary to show that

$$\sum_{k=1}^{\infty}\frac{\theta^k}{k!}\,\mathbb{E}\big[X^k\big]^{\frac{1}{p}}=\infty \text{ for }\theta>e^{\kappa/p}\quad\Longleftrightarrow\quad\limsup_{k\uparrow\infty}\frac{1}{k}\log\mathbb{E}\Big[\frac{X^k}{(k!)^p}\Big]\geq-\kappa\,.$$

Hence the *lower bound* in Theorem 2 is proved once we show that

(i) the limit $\kappa:=-\lim\limits_{k\uparrow\infty}\frac{1}{k}\log\mathbb{E}\big[\frac{I^k}{(k!)^p}\big]$ exists,

(ii) if there exists $h\geq 0$ with $\|h\|_q=\theta$ such that $\|\mathfrak{A}_h\|>1$ then $\sum_{k=1}^{\infty}\frac{\theta^k}{k!}\,\mathbb{E}\big[I^k\big]^{\frac{1}{p}}=\infty$.

The *proof of (i)* is accomplished in Section 2.2 using a subadditivity argument. As a by-product of this proof we see that for the upper tail behaviour of I it is irrelevant whether we start summation in the definition of I at time zero or one. The *proof of (ii)* is based on the precise formula (11) for the integer moments, which we derive in Section 2.3. Here the peculiarities of the discrete time structure can be quickly explained: It is easy to see that

$$\mathbb{E}\big[I^k\big]=\sum_{x_1,\ldots,x_k\in\mathbb{Z}^d}\Big(\sum_{i_1,\ldots,i_k}\mathbb{E}\prod_{\ell=1}^{k}\mathbb{1}\{X(i_\ell)=x_\ell\}\Big)^p,$$

where X is a random walk with the same law as $X^{(1)}, \dots, X^{(p)}$. To evaluate the expectation we need to keep track of indices with $i_k = i_\ell$ with $k < \ell$ as

$$\mathbb{1}\{X(i_k) = x_k, \, X(i_\ell) = x_\ell\} = \begin{cases} \mathbb{1}\{X(i_k) = x_k\} & \text{if } x_k = x_\ell, \\ 0 & \text{if } x_k \neq x_\ell. \end{cases}$$

This 'diagonal effect' cannot be neglected and we need to keep track of the number of equal indices in $(i_1, \dots, i_k)$. This leads to a significantly more complicated combinatorial structure of the moment formula and, ultimately, to the difference between the tail behaviour in the discrete and continuous time case. Having formulated a moment formula which keeps track of this effect, in Section 2.4, we insert it in the exponential series in *(ii)* and verify divergence of the series using first Hölder's inequality and then a spectral argument. This completes the proof of the lower bound in Theorem 2.

The proof of the *upper bound* is more delicate. We again use *(i)* and the formula (11) to reduce the problem to studying the large moment asymptotics of an explicit analytical quantity. However the use of spectral arguments, which was so successful for the lower bound, now seems to be confined to studying intersection local times in *finite* sets. Using similar ideas we show in Section 2.5 that, for any finite set $A \subset \mathbb{Z}^d$,

$$\limsup_{k \uparrow \infty} \frac{1}{k} \log \frac{1}{k!} \mathbb{E}[I(A)^k] \leq -p \log \inf \big\{ \|h\|_q \, : \, h \geq 0, \, \mathrm{supp}\, h \subset A \text{ with } \|\mathfrak{A}_h\| \geq 1 \big\}.$$

As indicated in Remark 1(c), the extension of the result from finite sets A to the entire lattice is highly nontrivial, because the problem is not exponentially tight. To overcome this difficulty, we need to project the full problem onto a finite domain by wrapping it around a torus. More precisely, in Section 2.6 we let $A = [-N, N)^d$ for a large integer N and show that

$$\limsup_{k \uparrow \infty} \frac{1}{k} \log \frac{1}{k!} \mathbb{E}[I^k] \leq -p \log \inf \big\{ \|h\|_q \, : \, h \geq 0, \, \mathrm{supp}\, h \subset A \text{ with } \|\widetilde{\mathfrak{A}}_{h,N}\| \geq 1 \big\},$$

where in the definition of the operator $\widetilde{\mathfrak{A}}_{h,N}$ the kernel $\mathbb{G}$ has been replaced by $\widetilde{\mathbb{G}}_N$ defined by

$$\widetilde{\mathbb{G}}_N(y) = \Big\{ \sum_{z \in \mathbb{Z}^d} \mathbb{G}^p \big(2Nz + y\big) \Big\}^{\frac{1}{p}} \qquad \text{for any } y \in \mathbb{Z}^d.$$

In Section 2.7 we let the period of the torus go to infinity and prove that

$$\limsup_{N \to \infty} \inf \big\{ \|h\|_q \, : \, h \geq 0, \, \mathrm{supp}\, h \subset A \text{ with } \|\widetilde{\mathfrak{A}}_{h,N}\| \geq 1 \big\} \geq \inf \big\{ \|h\|_q \, : \, h \geq 0 \text{ with } \|\mathfrak{A}_h\| \geq 1 \big\},$$

which leads to the required upper bound.

2.1 Proof of Lemma 1.

We start by showing that $\mathbb{G} \in L^p(\mathbb{Z}^d)$. Indeed, by [Uc98, (1.4)], we have (using only finite variance of the increments and the fact that the walk is aperiodic),

$$\mathbb{G}(z) \leq \sum_{x \in \mathbb{Z}^d} \frac{\pi(x)}{1 + |x - z|^{d-2}} \qquad \text{for all } z \in \mathbb{Z}^d,$$

where $(\pi(x) \colon x \in \mathbb{Z}^d)$ is a summable family of nonnegative weights. Hence, as $p(d-2) > d$,

$$\Big(\sum_{z \in \mathbb{Z}^d} \mathbb{G}^p(z) \Big)^{\frac{1}{p}} \leq \sum_{x \in \mathbb{Z}^d} \Big(\sum_{z \in \mathbb{Z}^d} \frac{\pi^p(x)}{(1 + |x - z|^{d-2})^p} \Big)^{\frac{1}{p}} = \Big(\sum_{x \in \mathbb{Z}^d} \pi(x) \Big) \Big(\sum_{z \in \mathbb{Z}^d} \frac{1}{(1 + |z|^{d-2})^p} \Big)^{\frac{1}{p}} < \infty.$$

To prove that the operator $\mathfrak{A}_h$ is bounded note that, whenever $\|g_1\|_2 = \|g_2\|_2 = 1$ and $g_1, g_2 \geq 0$, by Hölder's inequality,

$$
\begin{aligned}
\langle g_1, \mathfrak{A}_h g_2 \rangle &= \sum_{x,y \in \mathbb{Z}^d} g_1(x) \sqrt{e^{h(x)} - 1}\, \mathbb{G}(x-y)\, \sqrt{e^{h(y)} - 1}\, g_2(y) \\
&\leq \Big(\sum_{x,y \in \mathbb{Z}^d} \mathbb{G}^p(x-y) \big\{ g_1(x) \sqrt{e^{h(x)} - 1}\, g_2(y) \sqrt{e^{h(y)} - 1} \big\}^{\frac{p}{2p-1}} \Big)^{\frac{1}{p}} \\
&\quad \times \Big(\sum_{x,y \in \mathbb{Z}^d} \big\{ g_1(x) \sqrt{e^{h(x)} - 1}\, g_2(y) \sqrt{e^{h(y)} - 1} \big\}^{\frac{2p}{2p-1}} \Big)^{\frac{1}{q}}.
\end{aligned}
\tag{7}
$$

Using again Hölder's inequality, the *second factor* on the right hand side of (7) is bounded by

$$
\begin{aligned}
&\Big(\sum_{x \in \mathbb{Z}^d} \big\{ g_1(x) \sqrt{e^{h(x)} - 1} \big\}^{\frac{2p}{2p-1}} \Big)^{\frac{1}{q}} \Big(\sum_{x \in \mathbb{Z}^d} \big\{ g_2(x) \sqrt{e^{h(x)} - 1} \big\}^{\frac{2p}{2p-1}} \Big)^{\frac{1}{q}} \\
&\qquad \leq \Big(\sum_{x \in \mathbb{Z}^d} g_1^2(x) \Big)^{\frac{1}{q+1}} \Big(\sum_{x \in \mathbb{Z}^d} g_2^2(x) \Big)^{\frac{1}{q+1}} \Big(\big\{ \sum_{x \in \mathbb{Z}^d} (e^{h(x)} - 1)^q \big\}^{\frac{1}{q}} \Big)^{\frac{2}{q+1}},
\end{aligned}
$$

whence we use that $\|g_1\|_2 = \|g_2\|_2 = 1$ and

$$
\Big\{ \sum_{x \in \mathbb{Z}^d} (e^{h(x)} - 1)^q \Big\}^{\frac{1}{q}} \leq \sum_{k=1}^{\infty} \frac{\|h\|_q^k}{k!} \Big\{ \sum_{x \in \mathbb{Z}^d} \Big(\frac{h(x)}{\|h\|_q} \Big)^{kq} \Big\}^{\frac{1}{q}} \leq e^{\|h\|_q} - 1.
$$

By a shift of coordinates the *first factor* on the right hand side of (7) equals

$$
\Big(\sum_{x \in \mathbb{Z}^d} \mathbb{G}^p(x) \sum_{y \in \mathbb{Z}^d} \big\{ g_1(x+y) \sqrt{e^{h(x+y)} - 1}\, g_2(y) \sqrt{e^{h(y)} - 1} \big\}^{\frac{p}{2p-1}} \Big)^{\frac{1}{p}},
$$

and, using the Cauchy-Schwarz inequality, a further shift and Hölder's inequality,

$$
\begin{aligned}
&\sum_{y \in \mathbb{Z}^d} \big\{ g_1(x+y) \sqrt{e^{h(x+y)} - 1}\, g_2(y) \sqrt{e^{h(y)} - 1} \big\}^{\frac{p}{2p-1}} \\
&\qquad \leq \Big(\sum_{y \in \mathbb{Z}^d} \big\{ g_1(x+y) \sqrt{e^{h(x+y)} - 1} \big\}^{\frac{2p}{2p-1}} \Big)^{\frac{1}{2}} \Big(\sum_{y \in \mathbb{Z}^d} \big\{ g_2(y) \sqrt{e^{h(y)} - 1} \big\}^{\frac{2p}{2p-1}} \Big)^{\frac{1}{2}} \\
&\qquad \leq \Big(\sum_{y \in \mathbb{Z}^d} g_1^2(y) \Big)^{\frac{p}{4p-2}} \Big(\sum_{y \in \mathbb{Z}^d} g_2^2(y) \Big)^{\frac{p}{4p-2}} \Big(\sum_{y \in \mathbb{Z}^d} \big\{ e^{h(y)} - 1 \big\}^q \Big)^{\frac{p-1}{2p-1}} \leq \big(e^{\|h\|_q} - 1 \big)^{\frac{q}{q+1}}.
\end{aligned}
$$

Combining all these estimates we obtain that

$$
\langle g_1, \mathfrak{A}_h g_2 \rangle \leq \Big(\sum_{y \in \mathbb{Z}^d} \mathbb{G}(y)^p \Big)^{\frac{1}{p}} \big(e^{\|h\|_q} - 1 \big),
$$

which implies that $\mathfrak{A}_h$ is bounded and its spectral radius satisfies (2).

2.2 Existence of the high moment limit of intersection local time

We define the 'augmented' intersection local time I_0 by

$$
I_0 := \sum_{i_1,\dots,i_p=0}^{\infty} \mathbb{1}\{ X^{(1)}(i_1) = \cdots = X^{(p)}(i_p) \}.
$$

Lemma 4. *The limit* $\kappa_0 := -\lim_{k \to \infty} \frac{1}{k} \log \frac{\mathbb{E}[I_0^k]}{(k!)^p}$ *exists.*

Proof. By the subadditivity lemma it suffices to show that, for any $k, l \geq 1$,

$$\mathbb{E}\big[I_0^{k+l}\big]^{1/p} \leq \binom{k+l}{k} \mathbb{E}\big[I_0^k\big]^{1/p} \mathbb{E}\big[I_0^l\big]^{1/p}. \tag{8}$$

By X we denote a random walk with the same law as $X^{(1)}, \ldots, X^{(p)}$ and define its local time in x by $\ell(x) := \sum_{j=0}^{\infty} \mathbb{1}\{X(j) = x\}$. Then

$$\mathbb{E}\big[I_0^{k+l}\big] = \sum_{x_1,\ldots,x_{k+l} \in \mathbb{Z}^d} \left\{ \mathbb{E} \prod_{j=1}^{k+l} \ell(x_j) \right\}^p$$

$$= \sum_{x_1,\ldots,x_{k+l} \in \mathbb{Z}^d} \left\{ \sum_{i_1,\ldots,i_{k+l}=0}^{\infty} \mathbb{E} \prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right\} \left\{ \mathbb{E} \prod_{j=1}^{k+l} \ell(x_j) \right\}^{p-1}$$

$$= \sum_{i_1,\ldots,i_{k+l}=0}^{\infty} \sum_{x_1,\ldots,x_{k+l} \in \mathbb{Z}^d} \left\{ \mathbb{E} \prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right\} \left\{ \mathbb{E} \prod_{j=1}^{k+l} \ell(x_j) \right\}^{p-1}.$$

For any two vectors $(j_1, \ldots, j_k)$ and $(j_{k+1}, \ldots, j_{k+l})$ we write

$$(j_1, \ldots, j_k) \prec (j_{k+1}, \ldots, j_{k+l}) \quad \Longleftrightarrow \quad \max\{j_1, \ldots, j_k\} \leq \min\{j_{k+1}, \ldots, j_{k+l}\}.$$

Instead of choosing the vector $(i_1, \ldots, i_{k+l})$ directly, we may first pick k out of $k+l$ coordinates, then pick two vectors $(j_1, \ldots, j_k) \prec (j_{k+1}, \ldots, j_{k+l})$ and fill the chosen k coordinates successively with the entries of $(j_1, \ldots, j_k)$ and the remaining coordinates with the entries of $(j_{k+1}, \ldots, j_{k+l})$. Using this procedure and the permutation invariance we get

$$\mathbb{E}\big[I_0^{k+l}\big] \leq \binom{k+l}{k} \sum_{\substack{(i_1,\ldots,i_k) \\ \prec (i_{k+1},\ldots,i_{k+l})}} \sum_{x_1,\ldots,x_{k+l}} \left\{ \mathbb{E} \prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right\} \left\{ \mathbb{E} \prod_{j=1}^{k+l} \ell(x_j) \right\}^{p-1}.$$

Thus, using Hölder's inequality in the second step,

$$\mathbb{E}\big[I_0^{k+l}\big] \leq \binom{k+l}{k} \sum_{x_1,\ldots,x_{k+l}} \left\{ \sum_{\substack{(i_1,\ldots,i_k) \\ \prec (i_{k+1},\ldots,i_{k+l})}} \mathbb{E} \prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right\} \left\{ \mathbb{E} \prod_{j=1}^{k+l} \ell(x_j) \right\}^{p-1}$$

$$\leq \binom{k+l}{k} \left\{ \sum_{x_1,\ldots,x_{k+l}} \left(\sum_{\substack{(i_1,\ldots,i_k) \\ \prec (i_{k+1},\ldots,i_{k+l})}} \mathbb{E} \prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right)^p \right\}^{\frac{1}{p}} \left\{ \sum_{x_1,\ldots,x_{k+l}} \left(\mathbb{E} \prod_{j=1}^{k+l} \ell(x_j) \right)^p \right\}^{\frac{p-1}{p}}.$$

As the last factor equals $(\mathbb{E}[I_0^{k+l}])^{\frac{p-1}{p}}$ we get

$$\left(\mathbb{E}\big[I_0^{k+l}\big] \right)^{\frac{1}{p}} \leq \binom{k+l}{k} \left\{ \sum_{x_1,\ldots,x_{k+l} \in \mathbb{Z}^d} \left(\sum_{\substack{(i_1,\ldots,i_k) \\ \prec (i_{k+1},\ldots,i_{k+l})}} \mathbb{E} \prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right)^p \right\}^{\frac{1}{p}}. \tag{9}$$

Writing $i_* = \max\{i_1, \ldots, i_k\}$ we have

$$\mathbb{E} \prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} = \left\{ \mathbb{E} \prod_{j=1}^{k} \mathbb{1}\{X(i_j) = x_j\} \right\} \left\{ \mathbb{E} \prod_{j=k+1}^{k+l} \mathbb{1}\{X(i_j - i_*) = x_j - x_{i_*}\} \right\},$$

and therefore

$$\sum_{\substack{(i_1,\ldots,i_k) \\ \prec (i_{k+1},\ldots,i_{k+l})}} \mathbb{E}\prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\}$$

$$= \sum_{i_1,\ldots,i_k=0}^{\infty} \left\{ \mathbb{E}\prod_{j=1}^{k} \mathbb{1}\{X(i_j) = x_j\} \right\} \left\{ \sum_{i_{k+1},\ldots,i_{k+l}=0}^{\infty} \mathbb{E}\prod_{j=k+1}^{k+l} \mathbb{1}\{X(i_j) = x_j - x_{i_*}\} \right\}$$

$$= \sum_{i_1,\ldots,i_k=0}^{\infty} \left\{ \mathbb{E}\prod_{j=1}^{k} \mathbb{1}\{X(i_j) = x_j\} \right\} \left\{ \mathbb{E}\prod_{j=k+1}^{k+l} \ell(x_j - x_{i_*}) \right\}.$$

Thus

$$\sum_{x_1,\ldots,x_{k+l}\in\mathbb{Z}^d} \left\{ \sum_{\substack{(i_1,\ldots,i_k) \\ \prec (i_{k+1},\ldots,i_{k+l})}} \mathbb{E}\prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right\}^p$$

$$= \sum_{x_1,\ldots,x_{k+l}\in\mathbb{Z}^d} \prod_{h=1}^{p} \left(\sum_{i_1^h,\ldots,i_k^h=0}^{\infty} \left\{ \mathbb{E}\prod_{j=1}^{k} \mathbb{1}\{X(i_j^h) = x_j\} \right\} \left\{ \mathbb{E}\prod_{j=k+1}^{k+l} \ell(x_j - x_{i_*^h}) \right\} \right)$$

$$= \sum_{x_1,\ldots,x_k\in\mathbb{Z}^d} \left(\prod_{h=1}^{p} \sum_{i_1^h,\ldots,i_k^h=0}^{\infty} \left\{ \mathbb{E}\prod_{j=1}^{k} \mathbb{1}\{X(i_j^h) = x_j\} \right\} \right) \sum_{x_{k+1},\ldots,x_{k+l}\in\mathbb{Z}^d} \prod_{h=1}^{p} \left\{ \mathbb{E}\prod_{j=k+1}^{k+l} \ell(x_j - x_{i_*^h}) \right\}.$$

By Hölder's inequality

$$\sum_{x_{k+1},\ldots,x_{k+l}\in\mathbb{Z}^d} \prod_{h=1}^{p} \left\{ \mathbb{E}\prod_{j=k+1}^{k+l} \ell(x_j - x_{i_*^h}) \right\}$$

$$\leq \prod_{h=1}^{p} \left\{ \sum_{x_{k+1},\ldots,x_{k+l}\in\mathbb{Z}^d} \left\{ \mathbb{E}\prod_{j=k+1}^{k+l} \ell(x_j - x_{i_*^h}) \right\}^p \right\}^{1/p} = \mathbb{E}[I_0^l],$$

and thus

$$\sum_{x_1,\ldots,x_{k+l}\in\mathbb{Z}^d} \left\{ \sum_{\substack{(i_1,\ldots,i_k) \\ \prec (i_{k+1},\ldots,i_{k+l})}} \mathbb{E}\prod_{j=1}^{k+l} \mathbb{1}\{X(i_j) = x_j\} \right\}^p$$

$$\leq \mathbb{E}[I_0^l] \sum_{x_1,\ldots,x_k\in\mathbb{Z}^d} \prod_{h=1}^{p} \sum_{i_1^h,\ldots,i_k^h=0}^{\infty} \left\{ \mathbb{E}\prod_{j=1}^{k} \mathbb{1}\{X(i_j^h) = x_j\} \right\} = \mathbb{E}[I_0^l]\mathbb{E}[I_0^k],$$

which together with (9) proves (8) and thus completes the proof. $\qquad\square$

Lemma 5. *The limit* $\kappa := -\lim_{k\to\infty} \dfrac{1}{k} \log \dfrac{\mathbb{E}[I^k]}{(k!)^p}$ *exists and is equal to* κ_0.

Proof. To make the passage from I_0 to I first note that $I \leq I_0$, and hence we have

$$\limsup_{k\to\infty} \frac{1}{k} \log \frac{1}{(k!)^p} \mathbb{E}[I^k] \leq -\kappa_0.$$

Hence only the converse inequality needs to be proved. Define the local times

$$\ell_j(x) := \sum_{k=0}^{\infty} \mathbb{1}\{X^{(j)}(k) = x\} \qquad \text{for } x \in \mathbb{Z}^d.$$

Then we obtain

$$I_0 \leq I + \sum_{j=1}^{p} \prod_{\substack{i=1 \\ i \neq j}}^{p} \ell_i(0) \, ,$$

and thus, by the triangle inequality,

$$\mathbb{E}\big[I_0^k\big]^{1/k} \leq \mathbb{E}\big[I^k\big]^{1/k} + \mathbb{E}\Big[\Big(\sum_{j=1}^{p} \prod_{\substack{i=1 \\ i \neq j}}^{p} \ell_i(0)\Big)^k\Big]^{1/k}. \tag{10}$$

For the second term we get, using the multinomial theorem,

$$\mathbb{E}\Big[\Big(\sum_{j=1}^{p} \prod_{\substack{i=1 \\ i \neq j}}^{p} \ell_i(0)\Big)^k\Big] = \sum_{\substack{k_1 + \cdots + k_p = k \\ k_1, \ldots, k_p \geq 0}} \frac{k!}{k_1! \cdots k_p!} \prod_{i=1}^{p} \mathbb{E}\big[\ell_i(0)^{\sum_{j \neq i} k_j}\big] \, .$$

As $X = \ell_i(0)$ is a geometric random variable and hence $\mathbb{E}[e^{\lambda X}] < \infty$ for some $\lambda > 0$, we get

$$\mathbb{E}\big[\ell_i(0)^n\big] \leq n! \, \mathbb{E}[e^{\lambda X}] \, \lambda^{-n}.$$

Hence, for a suitable constant $C > 0$,

$$\mathbb{E}\Big[\Big(\sum_{j=1}^{p} \prod_{\substack{i=1 \\ i \neq j}}^{p} \ell_i(0)\Big)^k\Big] \leq \mathbb{E}\big[e^{\lambda X}\big]^p \, \lambda^{-k(p-1)} \sum_{\substack{k_1 + \cdots + k_p = k \\ k_1, \ldots, k_p \geq 0}} \frac{k!}{k_1! \cdots k_p!} \prod_{i=1}^{p} \Big(\sum_{\substack{j=1 \\ j \neq i}}^{p} k_j\Big)! \leq C^k \, (k!)^{p-1} \, ,$$

which implies

$$\liminf_{k \to \infty} \frac{1}{k} \log \frac{1}{(k!)^p} \mathbb{E}\Big[\Big(\sum_{j=1}^{p} \prod_{\substack{i=1 \\ i \neq j}}^{p} \ell_i(0)\Big)^k\Big] = -\infty \, .$$

The result thus follows from (10). $\qquad \square$

2.3 The integer moments of intersection local time

We define, for any $1 \leq m \leq k$, the family of all m-partitions of the set $\{1, \ldots, k\}$ as

$$\mathcal{E}_m := \big\{\pi = (\pi_1, \ldots, \pi_m) \, : \, \pi_j \neq \emptyset \text{ with } \pi_i \cap \pi_j = \emptyset \text{ for all } i \neq j \text{ and } \bigcup_{j=1}^{m} \pi_j = \{1, \ldots, k\}\big\},$$

where we assume that the elements $\pi_1, \ldots, \pi_m$ of an m-partition are ordered by increasing order of their minimal elements. To any $(i_1, \ldots, i_k) \in \mathbb{N}^k$ we associate

- a tuple $(i_1^*, \ldots, i_m^*)$ of distinct natural numbers such that $\{i_1, \ldots, i_k\} = \{i_1^*, \ldots, i_m^*\}$ and elements in the tuple $(i_1^*, \ldots, i_m^*)$ appear in the order in which they appear first in $(i_1, \ldots, i_k)$;
- an m-partition $(\pi_1, \ldots, \pi_m) \in \mathcal{E}_m$ with $i_j = i_\ell^*$ whenever $j \in \pi_\ell$.

Conversely, given a tuple $(j_1, \ldots, j_m)$ of distinct natural numbers and an m-partition π we can find $(i_1, \ldots, i_k) \in \mathbb{N}^k$ such that the induced m-tuple is $(j_1, \ldots, j_m)$ and the induced m-partition is π.

Define the family of k-tuples of points in $\mathbb{Z}^d$ associated to some $\pi \in \mathcal{E}_m$ by

$$\mathcal{A}(\pi) := \big\{(x_1, \ldots, x_k) \in (\mathbb{Z}^d)^k \, : \, x_i = x_j \text{ for all } i, j \in \pi_\ell \text{ and } \ell \in \{1, \ldots, m\}\big\}.$$

For any $(x_1, \ldots, x_k) \in \mathcal{A}(\pi)$ and for any $1 \leq \ell \leq m$, we use x_{π_ℓ} for the common value of $\{x_j : j \in \pi_\ell\}$. Observing that

$$X(i_\ell) = x_\ell \text{ for all } \ell \in \{1, \ldots, k\}$$

$$\Leftrightarrow \quad (x_1, \ldots, x_k) \in \mathcal{A}(\pi) \text{ and } X(i_\ell^*) = x_{\pi_\ell} \text{ for all } \ell \in \{1, \ldots, m\},$$

we get that

$$\mathbb{E}[I^k] = \sum_{x_1,\ldots,x_k \in \mathbb{Z}^d} \Big(\sum_{i_1,\ldots,i_k} \mathbb{E} \prod_{\ell=1}^k \mathbb{1}\{X(i_\ell) = x_\ell\} \Big)^p$$

$$= \sum_{x_1,\ldots,x_k \in \mathbb{Z}^d} \Big(\sum_{m=1}^k \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k) \in \mathcal{A}(\pi)\} \sum_{\substack{j_1,\ldots,j_m \\ \text{distinct}}} \mathbb{E} \prod_{\ell=1}^m \mathbb{1}\{X(j_\ell) = x_{\pi_\ell}\} \Big)^p,$$

and therefore, using $\mathfrak{S}_m$ to denote the symmetric group on m elements,

$$\mathbb{E}[I^k] = \sum_{x_1,\ldots,x_k \in \mathbb{Z}^d} \Big(\sum_{m=1}^k \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^m \mathbb{G}\big(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}}\big) \Big)^p, \tag{11}$$

where we use the convention that $x_{\pi_{\sigma(0)}} := 0$.

2.4 The lower bound in Theorem 2

Based on (11) we now complete the proof of the lower bound in Theorem 2. We will repeatedly make use of the following two simple facts:

- For any $\pi \in \mathcal{E}_m$, the map

$$\Phi \colon \mathcal{A}(\pi) \to (\mathbb{Z}^d)^m, \qquad (x_1,\ldots,x_k) \mapsto (x_{\pi_1},\ldots,x_{\pi_m})$$

  is one-to-one and onto, i.e. a bijection.

- For any $j_1,\ldots,j_m \geq 1$ with $j_1 + \cdots + j_m = k$, we have

$$\#\big\{\pi = (\pi_1,\cdots,\pi_m) \in \mathcal{E}_m \,:\, \#(\pi_\ell) = j_\ell \text{ for all } \ell \in \{1,\ldots,m\}\big\} = \frac{1}{m!} \frac{k!}{j_1! \cdots j_m!}.$$

Recall from our outline that, given Lemma 5, in order to verify the lower bound in Theorem 2 it suffices to establish the following lemma.

Lemma 6. *If there exists $h \geq 0$ with $\|h\|_q \leq \theta$ such that $\|\mathfrak{A}_h\| > 1$, then*

$$\sum_{k=1}^\infty \frac{\theta^k}{k!} \mathbb{E}[I^k]^{\frac{1}{p}} = \infty.$$

Proof. Let $h \geq 0$ with $\|h\|_q \leq \theta$. Then, using Hölder's inequality in the first step,

$$\theta^k \mathbb{E}[I^k]^{\frac{1}{p}} \geq \sum_{x_1,\ldots,x_k \in \mathbb{Z}^d} \Big(\prod_{j=1}^k h(x_j) \Big) \sum_{m=1}^k \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^m \mathbb{G}\big(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}}\big)$$

$$= \sum_{m=1}^k \sum_{\sigma \in \mathfrak{S}_m} \sum_{\pi \in \mathcal{E}_m} \sum_{x_1,\ldots,x_k \in \mathbb{Z}^d} \Big(\prod_{\ell=1}^m h(x_{\pi_\ell})^{\#(\pi_\ell)} \Big) \Big(\prod_{\ell=1}^m \mathbb{G}\big(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}}\big) \Big)$$

$$= \sum_{m=1}^k \sum_{\sigma \in \mathfrak{S}_m} \sum_{\pi \in \mathcal{E}_m} \sum_{x_1,\ldots,x_m \in \mathbb{Z}^d} \Big(\prod_{\ell=1}^m h(x_\ell)^{\#(\pi_\ell)} \Big) \Big(\prod_{\ell=1}^m \mathbb{G}\big(x_{\sigma(\ell)} - x_{\sigma(\ell-1)}\big) \Big),$$

where we use the convention $x_{\sigma(0)} := 0$, and the last step follows from the one-to-one correspondence between $\mathcal{A}(\pi)$ and $\mathbb{Z}^m$. Therefore,

$$\theta^k \, \mathbb{E}\big[I^k\big]^{\frac{1}{p}} \geq \sum_{m=1}^{k} m! \sum_{x_1,\ldots,x_m \in \mathbb{Z}^d} \sum_{\pi \in \mathcal{E}_m} \bigg(\prod_{\ell=1}^{m} h(x_\ell)^{\#(\pi_\ell)}\bigg)\bigg(\prod_{\ell=1}^{m} \mathbb{G}(x_\ell - x_{\ell-1})\bigg)$$

$$= \sum_{m=1}^{k} \sum_{x_1,\ldots,x_m \in \mathbb{Z}^d} \sum_{\substack{j_1+\cdots+j_m=k \\ j_1,\ldots,j_m \geq 1}} \frac{k!}{j_1! \cdots j_m!} \bigg(\prod_{\ell=1}^{m} h(x_\ell)^{j_\ell}\bigg)\bigg(\prod_{\ell=1}^{m} \mathbb{G}(x_\ell - x_{\ell-1})\bigg),$$

where we use the convention $x_0 := 0$. Thus

$$\sum_{k=1}^{\infty} \frac{\theta^k}{k!} \, \mathbb{E}\big[I^k\big]^{\frac{1}{p}} \geq \sum_{m=1}^{\infty} \sum_{k=m}^{\infty} \sum_{x_1,\ldots,x_m} \bigg\{ \sum_{\substack{j_1+\cdots+j_m=k \\ j_1,\ldots,j_m \geq 1}} \frac{1}{j_1! \cdots j_m!} \bigg(\prod_{\ell=1}^{m} h(x_\ell)^{j_\ell}\bigg)\bigg\}\bigg(\prod_{\ell=1}^{m} \mathbb{G}(x_\ell - x_{\ell-1})\bigg)$$

$$= \sum_{m=1}^{\infty} \sum_{x_1,\ldots,x_m} \bigg\{ \prod_{\ell=1}^{m} \sum_{j=1}^{\infty} \frac{h(x_\ell)^j}{j!} \bigg\}\bigg(\prod_{\ell=1}^{m} \mathbb{G}(x_\ell - x_{\ell-1})\bigg) \tag{12}$$

$$= \sum_{m=1}^{\infty} \sum_{x_1,\ldots,x_m} \prod_{\ell=1}^{m} \big(e^{h(x_\ell)} - 1\big) \, \mathbb{G}(x_\ell - x_{\ell-1}) \, .$$

Now assume that h additionally satisfies $\|\mathfrak{A}_h\| > 1$. Fix $\varepsilon > 0$ such that $\|\mathfrak{A}_h\| > e^\varepsilon$ and $g \geq 0$ with $\|g\|_2 = 1$ such that $\langle g, \mathfrak{A}_h g\rangle > e^\varepsilon$. By monotone convergence we may find a finite set $A \subset \mathbb{Z}^d$ such that

$$\big\langle g\mathbb{1}_A, \mathfrak{A}_h\big(g\mathbb{1}_A\big)\big\rangle > e^\varepsilon \quad \text{and} \quad \|g\mathbb{1}_A\|_2 > e^{-\varepsilon},$$

and additionally, but without loss of generality, $g, h > 0$ on A. We infer that there exists $\delta > 0$ with

$$\big(\inf_{y \in A} \mathbb{G}(y)\big) \big(e^{h(x)} - 1\big) \geq \delta \, g^2(x) \, \mathbb{1}_A(x) \qquad \text{for all } x \in \mathbb{Z}^d.$$

Hence

$$\sum_{x_1,\ldots,x_m \in \mathbb{Z}^d} \prod_{\ell=1}^{m} \big(e^{h(x_\ell)} - 1\big) \, \mathbb{G}(x_\ell - x_{\ell-1})$$

$$= \sum_{x_1,\ldots,x_m \in \mathbb{Z}^d} \mathbb{G}(x_1) \sqrt{e^{h(x_1)} - 1} \bigg[\prod_{\ell=2}^{m} \sqrt{e^{h(x_{\ell-1})} - 1} \, \mathbb{G}(x_\ell - x_{\ell-1}) \sqrt{e^{h(x_\ell)} - 1}\bigg] \sqrt{e^{h(x_m)} - 1}$$

$$\geq \delta \sum_{x_1,\ldots,x_m \in \mathbb{Z}^d} g(x_1)\mathbb{1}_A(x_1) \bigg[\prod_{\ell=2}^{m} \sqrt{e^{h(x_{\ell-1})} - 1} \, \mathbb{G}(x_\ell - x_{\ell-1}) \sqrt{e^{h(x_\ell)} - 1}\bigg] g(x_m)\mathbb{1}_A(x_m)$$

$$= \delta\big\langle g\mathbb{1}_A, \mathfrak{A}_h^{m-1}(g\mathbb{1}_A)\big\rangle \, .$$

By the spectral theorem, see for example [He82, 79.1], for any $\tilde{g} \in L^2(\mathbb{Z}^d)$ with $\|\tilde{g}\|_2 = 1$ there exists a probability measure $\mu_{\tilde{g}}$ such that, for every $k \geq 0$,

$$\langle \tilde{g}, \mathfrak{A}_h^k \tilde{g}\rangle = \int_{-\infty}^{\infty} \theta^k \, \mu_{\tilde{g}}(d\theta) \, ,$$

and consequently, at least for even k,

$$\langle \tilde{g}, \mathfrak{A}_h^k \tilde{g}\rangle = \int_{-\infty}^{\infty} \theta^k \, \mu_{\tilde{g}}(d\theta) \geq \bigg(\int_{-\infty}^{\infty} \theta \, \mu_{\tilde{g}}(d\theta)\bigg)^k = \langle \tilde{g}, \mathfrak{A}_h \tilde{g}\rangle^k.$$

We infer that

$$\liminf_{\substack{m\uparrow\infty \\ m \text{ odd}}} \frac{1}{m} \log \sum_{x_1,\ldots,x_m\in\mathbb{Z}^d} \prod_{\ell=1}^{m} \left(e^{h(x_\ell)} - 1\right)\mathbb{G}(x_\ell - x_{\ell-1})$$

$$\geq \log \left\langle g\mathbb{1}_A, \mathfrak{A}_h(g\mathbb{1}_A)\right\rangle + \log \|g\mathbb{1}_A\|_2 > 0\,.$$

Combining this with (12) we see that the series $\sum \frac{\theta^k}{k!}\,\mathbb{E}\big[I^k\big]^{\frac{1}{p}}$ diverges, as claimed. $\qquad\square$

2.5 The upper bound for intersections in a finite set

We now assume that $A \subset \mathbb{Z}^d$ is a finite set and consider the intersection local time restricted to the set A, which is defined as $I(A)$ in Remark 1(b). The arguments of Section 2.3 show that

$$\mathbb{E}[I(A)^k] = \sum_{x_1,\ldots,x_k\in A} \left[\sum_{m=1}^{k} \sum_{\pi\in\mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k)\in\mathcal{A}(\pi)\} \sum_{\sigma\in\mathfrak{S}_m} \prod_{\ell=1}^{m} \mathbb{G}(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}})\right]^p.$$

We now provide an upper bound for the asymptotics of this expression as $k \uparrow \infty$, replacing (for later reference) Green's function wherever it occurs by an arbitrary symmetric kernel.

Lemma 7. *Suppose $G\colon \mathbb{Z}^d \to (0,\infty)$ is symmetric. Then*

$$\limsup_{k\uparrow\infty} \frac{1}{k} \log \frac{1}{k!} \sum_{x_1,\ldots,x_k\in A} \left[\sum_{m=1}^{k} \sum_{\pi\in\mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k)\in\mathcal{A}(\pi)\} \sum_{\sigma\in\mathfrak{S}_m} \prod_{\ell=1}^{m} G(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}})\right]^p$$

$$\leq -p \log\inf \big\{\|h\|_q\,:\, h \geq 0,\ \operatorname{supp} h \subset A \text{ with } \|\mathfrak{A}_h\| \geq 1\big\},$$

where the operator $\mathfrak{A}_h$ is associated with the kernel G.

Remark 5. With this lemma we have completed the proof of Remark 1(b). Indeed, the lower bound for the asymptotics of the intersection local times $I(A)$ in a finite set A follows from the arguments in Sections 2.1 and 2.3 simply replacing $\mathbb{Z}^d$ by A. For the upper bound use Lemma 7 with $G = \mathbb{G}$. $\qquad\square$

Proof. Fix a vector $\mathbf{x} = (x_1,\ldots,x_k)$ of length k with entries from the set A and associate its *empirical measure* $L_k^{\mathbf{x}}$ by letting

$$L_k^{\mathbf{x}} := \frac{1}{k} \sum_{j=1}^{k} \delta_{x_j}\,.$$

For each $\tau \in \mathfrak{S}_k$ and $\pi \in \mathcal{E}_m$ we denote by $\tau(\pi) \in \mathcal{E}_m$ the partition consisting of the sets $\tau(\pi)_\ell := \tau(\pi_\ell)$ for $\ell \in \{1\ldots,m\}$. Then, for any $\tau \in \mathfrak{S}_k$ and $\mathbf{x} = (x_1,\ldots,x_k)$, we get

$$\sum_{m=1}^{k} \sum_{\pi\in\mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k)\in\mathcal{A}(\pi)\} \sum_{\sigma\in\mathfrak{S}_m} \prod_{\ell=1}^{m} G(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}})$$

$$= \sum_{y_1,\ldots,y_k\in A} \mathbb{1}\{\mathbf{x} = \mathbf{y}\circ\tau\} \sum_{m=1}^{k} \sum_{\pi\in\mathcal{E}_m} \mathbb{1}\{(y_1,\ldots,y_k)\in\mathcal{A}(\tau(\pi))\} \sum_{\sigma\in\mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\tau(\pi_{\sigma(\ell)})} - y_{\tau(\pi_{\sigma(\ell-1)})})$$

$$= \sum_{y_1,\ldots,y_k\in A} \mathbb{1}\{\mathbf{x} = \mathbf{y}\circ\tau\} \sum_{m=1}^{k} \sum_{\pi\in\mathcal{E}_m} \mathbb{1}\{(y_1,\ldots,y_k)\in\mathcal{A}(\pi)\} \sum_{\sigma\in\mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})\,,$$

where we use the conventions $y_{\tau(\pi_{\sigma(0)})} := 0$, $y_{\pi_{\sigma(0)}} := 0$.

Observe that, abbreviating $\mu = L_k^{\mathbf{x}}$ and assuming $L_k^{\mathbf{y}} = L_k^{\mathbf{x}}$, we have

$$\sum_{\tau \in \mathfrak{S}_k} \mathbb{1}\{\mathbf{x} = \mathbf{y} \circ \tau\} = \prod_{x \in A} \big(k\mu(x)\big)!,$$

and hence summing the previous expression over all permutations $\tau \in \mathfrak{S}_k$ gives

$$k! \sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(x_1, \ldots, x_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}})$$

$$= \prod_{x \in A} \big(k\mu(x)\big)! \sum_{y_1, \ldots, y_k} \mathbb{1}\{L_k^{\mathbf{y}} = \mu\} \sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(y_1, \ldots, y_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}}).$$

Write $\phi_\mu(x) = \mu(x)^{1/q}$ for all $x \in A$ and note that

$$\sum_{y_1, \ldots, y_k} \mathbb{1}\{L_k^{\mathbf{y}} = \mu\} \sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(y_1, \ldots, y_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})$$

$$\leq \Big(\prod_{x \in A} \phi_\mu(x)^{-k\mu(x)} \Big) \sum_{y_1, \ldots, y_k} \phi_\mu(y_1) \cdots \phi_\mu(y_k) \sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(y_1, \ldots, y_k) \in \mathcal{A}(\pi)\}$$

$$\times \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}}).$$

Simplifying and finally using the expression for $\#\mathcal{E}_m$, we obtain

$$\sum_{y_1, \ldots, y_k} \phi_\mu(y_1) \cdots \phi_\mu(y_k) \sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(y_1, \ldots, y_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})$$

$$= \sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \sum_{y_1, \ldots, y_k} \mathbb{1}\{(y_1, \ldots, y_k) \in \mathcal{A}(\pi)\} \Big\{ \prod_{\ell=1}^{m} \phi_\mu(y_{\pi_\ell})^{\#(\pi_\ell)} \Big\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})$$

$$= \sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \sum_{y_1, \ldots, y_m} \Big\{ \prod_{\ell=1}^{m} \phi_\mu(y_\ell)^{\#(\pi_\ell)} \Big\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(y_{\sigma(\ell)} - y_{\sigma(\ell-1)})$$

$$= \sum_{m=1}^{k} m! \sum_{y_1, \ldots, y_m} \Big\{ \sum_{\pi \in \mathcal{E}_m} \prod_{\ell=1}^{m} \phi_\mu(y_\ell)^{\#(\pi_\ell)} \Big\} \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1})$$

$$= \sum_{m=1}^{k} \sum_{y_1, \ldots, y_m} \Big\{ \sum_{\substack{j_1 + \cdots + j_m = k \\ j_1, \ldots, j_m \geq 1}} \frac{k!}{j_1! \cdots j_m!} \prod_{\ell=1}^{m} \phi_\mu(y_\ell)^{j_\ell} \Big\} \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1}).$$

Further, using Stirling's formula, we obtain a fixed polynomial $P(\cdot)$, depending only on the cardinality of A, such that

$$\Big\{ \prod_{x \in A} \big(k\mu(x)\big)! \Big\} \Big\{ \prod_{x \in A} \phi_\mu(x)^{-k\mu(x)} \Big\} \leq P(k) \, k! \Big\{ \prod_{j=1}^{k} \mu(x_j)^{\frac{1}{p}} \Big\}.$$

Summarizing all what we have got so far

$$\sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}})$$

$$\leq P(k)\, k! \left\{ \prod_{j=1}^{k} \mu(x_j)^{\frac{1}{p}} \right\} \sum_{m=1}^{k} \sum_{y_1,\ldots,y_m \in A} \left\{ \sum_{\substack{j_1+\cdots+j_m=k \\ j_1,\ldots,j_m \geq 1}} \frac{1}{j_1! \cdots j_m!} \prod_{\ell=1}^{m} \phi_\mu^{j_\ell}(y_\ell) \right\} \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1}).$$

Summing over all possible vectors $\mathbf{x} = (x_1,\ldots,x_k)$ gives

$$I_k := \sum_{x_1,\ldots,x_k \in A} \left[\sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(x_1,\ldots,x_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} G(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}}) \right]^p$$

$$\leq P(k)^p \, (k!)^p \sup_{\mu \in \mathcal{P}_k(A)} \left[\sum_{m=1}^{k} \sum_{y_1,\ldots,y_m \in A} \left(\sum_{\substack{j_1+\cdots+j_m=k \\ j_1,\ldots,j_m \geq 1}} \frac{1}{j_1! \cdots j_m!} \prod_{\ell=1}^{m} \phi_\mu^{j_\ell}(y_\ell) \right) \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1}) \right]^p,$$

where $\mathcal{P}_k(A)$ stands for the set of probability densities ν on A such that $\nu(x)$ is of the form i/k. Recall that $\phi_\mu \geq 0$ satisfies $\|\phi_\mu\|_q = 1$ and hence we may replace the supremum by one over all L^q-normalised nonnegative functions on A. Thus, for every $\theta > 0$,

$$\frac{\theta^k}{k!} \left(I_k\right)^{\frac{1}{p}} \leq P(k) \sup_{\|f\|_q=1} \sum_{n=1}^{\infty} \theta^n \sum_{m=1}^{n} \sum_{y_1,\ldots,y_m \in A} \left(\sum_{\substack{j_1+\cdots+j_m=n \\ j_1,\ldots,j_m \geq 1}} \frac{1}{j_1! \cdots j_m!} \prod_{\ell=1}^{m} f^{j_\ell}(y_\ell) \right) \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1})$$

$$= P(k) \sup_{\|h\|_q=\theta} \sum_{m=1}^{\infty} \sum_{y_1,\ldots,y_m \in A} \left\{ \prod_{\ell=1}^{m} \sum_{j=1}^{\infty} \frac{h(y_\ell)^j}{j!} \right\} \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1})$$

$$= P(k) \sup_{\|h\|_q=\theta} \sum_{m=1}^{\infty} \sum_{y_1,\ldots,y_m \in A} \left\{ \prod_{\ell=1}^{m} \left(e^{h(y_\ell)} - 1 \right) \right\} \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1}).$$

Let $g(x) = [\#A]^{-1/2}$ for all $x \in A$ and note that $\|g\|_2 = 1$. Using that $0 \leq h(x) \leq \theta$ we obtain

$$\sum_{y_1,\ldots,y_m \in A} \left\{ \prod_{\ell=1}^{m} \left(e^{h(y_\ell)} - 1 \right) \right\} \prod_{\ell=1}^{m} G(y_\ell - y_{\ell-1})$$

$$\leq \left(\sup_{y \in A} G(y) \right) \left(e^\theta - 1 \right) \sum_{y_1,\ldots,y_m \in A} \prod_{\ell=2}^{m} \left\{ \sqrt{e^{h(y_{\ell-1})} - 1}\, G(y_\ell - y_{\ell-1}) \sqrt{e^{h(y_\ell)} - 1} \right\}$$

$$= \left(\sup_{y \in A} G(y) \right) \left(e^\theta - 1 \right) [\#A] \left\langle g, \mathfrak{A}_h^{m-1} g \right\rangle$$

$$\leq \left(\sup_{y \in A} G(y) \right) \left(e^\theta - 1 \right) [\#A] \left\| \mathfrak{A}_h \right\|^{m-1}.$$

Suppose that $\theta < \inf\{\|h\|_q : \operatorname{supp} h \subset A, \|\mathfrak{A}_h\| \geq 1\}$, then there exists $\epsilon > 0$ such that every h with $\|h\|_q = \theta$ satisfies $\|\mathfrak{A}_h\| < 1 - \epsilon$. We infer that

$$\frac{\theta^k}{k!} \left(I_k\right)^{\frac{1}{p}} \leq P(k) \left(\sup_{y \in A} G(y) \right) \left(e^\theta - 1 \right) [\#A] \sup_{\|h\|_q=\theta} \sum_{m=1}^{\infty} \left\| \mathfrak{A}_h \right\|^{m-1}.$$

As the suprema on the right hand side are both finite, we obtain

$$\limsup_{k \to \infty} \frac{1}{k} \log \frac{I_k}{(k!)^p} \leq -p \log \theta,$$

as required to complete the proof.   □

2.6 Wrapping the random walks around the torus

We now look back to the full lattice $\mathbb{Z}^d$ and discuss how to project the problem onto a finite set. We fix a large integer N an let $A_N := [-N, N)^d$. Then every $x \in \mathbb{Z}^d$ can uniquely be written as $x = 2Nz + y$ for $z \in \mathbb{Z}^d$ and $y \in A_N$. Hence, using Hölder's inequality in the second step,

$$
\mathbb{E}\big[I^k\big] = \sum_{y_1,\dots,y_k \in A_N} \sum_{z_1,\dots,z_k \in \mathbb{Z}^d} \bigg[\sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(2Nz_1 + y_1, \dots, 2Nz_k + y_k) \in \mathcal{A}(\pi)\}
$$
$$
\times \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} \mathbb{G}\big(2N(z_{\pi_{\sigma(\ell)}} - z_{\pi_{\sigma(\ell-1)}}) + (y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})\big) \bigg]^p
$$
$$
\leq \sum_{y_1,\dots,y_k \in A_N} \bigg[\sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \sum_{\sigma \in \mathfrak{S}_m} \bigg\{ \sum_{z_1,\dots,z_k \in \mathbb{Z}^d} \mathbb{1}\{(2Nz_1 + y_1, \dots, 2Nz_k + y_k) \in \mathcal{A}(\pi)\}
$$
$$
\times \prod_{\ell=1}^{m} \mathbb{G}^p\big(2N(z_{\pi_{\sigma(\ell)}} - z_{\pi_{\sigma(\ell-1)}}) + (y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})\big) \bigg\}^{1/p} \bigg]^p .
$$

From the uniqueness of the decomposition $x = 2Nz + y$ we infer that

$$
\mathbb{1}\{(2Nz_1 + y_1, \dots, 2Nz_k + y_k) \in \mathcal{A}(\pi)\} = \mathbb{1}\{(y_1, \dots, y_k) \in \mathcal{A}(\pi)\} \, \mathbb{1}\{(z_1, \dots, z_k) \in \mathcal{A}(\pi)\}.
$$

Therefore,

$$
\sum_{z_1,\dots,z_k \in \mathbb{Z}^d} \mathbb{1}\{(2Nz_1 + y_1, \dots, 2Nz_k + y_k) \in \mathcal{A}(\pi)\} \prod_{\ell=1}^{m} \mathbb{G}^p\big(2N(z_{\pi_{\sigma(\ell)}} - z_{\pi_{\sigma(\ell-1)}}) + (y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})\big)
$$
$$
= \mathbb{1}\{(y_1, \dots, y_k) \in \mathcal{A}(\pi)\} \sum_{z_1,\dots,z_k \in \mathbb{Z}^d} \mathbb{1}\{(z_1, \dots, z_k) \in \mathcal{A}(\pi)\}
$$
$$
\times \prod_{\ell=1}^{m} \mathbb{G}^p\big(2N(z_{\pi_{\sigma(\ell)}} - z_{\pi_{\sigma(\ell-1)}}) + (y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})\big)
$$
$$
= \mathbb{1}\{(y_1, \dots, y_k) \in \mathcal{A}(\pi)\} \sum_{z_1,\dots,z_m \in \mathbb{Z}^d} \prod_{\ell=1}^{m} \mathbb{G}^p\big(2N(z_{\sigma(\ell)} - z_{\sigma(\ell-1)}) + (y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}})\big)
$$
$$
= \mathbb{1}\{(y_1, \dots, y_k) \in \mathcal{A}(\pi)\} \prod_{\ell=1}^{m} \widetilde{\mathbb{G}}_N^p\big(y_{\pi_{\sigma(\ell)}} - y_{\pi_{\sigma(\ell-1)}}\big),
$$

where we define

$$
\widetilde{\mathbb{G}}_N(y) = \bigg\{ \sum_{z \in \mathbb{Z}^d} \mathbb{G}^p\big(2Nz + y\big) \bigg\}^{\frac{1}{p}} \qquad \text{for any } y \in \mathbb{Z}^d .
$$

Summarizing, we have shown that

$$
\mathbb{E}\big[I^k\big] \leq \sum_{x_1,\dots,x_k \in A_N} \bigg[\sum_{m=1}^{k} \sum_{\pi \in \mathcal{E}_m} \mathbb{1}\{(x_1, \dots, x_k) \in \mathcal{A}(\pi)\} \sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{m} \widetilde{\mathbb{G}}_N\big(x_{\pi_{\sigma(\ell)}} - x_{\pi_{\sigma(\ell-1)}}\big) \bigg]^p .
$$

We can now apply Lemma 7 and obtain

$$
\limsup_{k \uparrow \infty} \frac{1}{k} \log \frac{1}{k!} \, \mathbb{E}\big[I^k\big] \leq -p \log \inf \big\{ \|h\|_q \, : \, h \geq 0, \, \operatorname{supp} h \subset A_N \text{ with } \|\widetilde{\mathfrak{A}}_{h,N}\| \geq 1 \big\},
$$

where the self-adjoint operator $\widetilde{\mathfrak{A}}_{h,N} \colon L^2(\mathbb{Z}^d) \to L^2(\mathbb{Z}^d)$ is defined by

$$
\widetilde{\mathfrak{A}}_{h,N} g(x) = \sqrt{e^{h(x)} - 1} \sum_{y \in A_N} \widetilde{\mathbb{G}}_N(x - y) \sqrt{e^{h(y)} - 1} \, g(y) .
$$

2.7 The upper bound in Theorem 2

The proof of Theorem 2 is complete once we have proved the following lemma.

Lemma 8.

$$\limsup_{N\to\infty} \inf \left\{ \|h\|_q \,:\, h \geq 0 \text{ with } \|\widetilde{\mathfrak{A}}_{h,N}\| \geq 1 \right\} \geq \inf \left\{ \|h\|_q \,:\, h \geq 0 \text{ with } \|\mathfrak{A}_h\| \geq 1 \right\}.$$

Proof. Fix positive integers $M < N$ and define the annulus

$$E_N := \left\{ x \in A_N : |x| \geq N - M \right\}.$$

We decompose $\mathbb{G} = \mathbb{G}_+ + \mathbb{G}_-$ with $\mathbb{G}_+(x) = \mathbb{G}(x)\mathbb{1}\{|x| > M\}$ and $\mathbb{G}_-(x) = \mathbb{G}(x)\mathbb{1}\{|x| \leq M\}$. In analogy to $\widetilde{\mathbb{G}}_N$ we define symmetric, periodic functions $\widetilde{\mathbb{G}}_+$ and $\widetilde{\mathbb{G}}_-$ by

$$\widetilde{\mathbb{G}}_{\pm}(y) = \left\{ \sum_{z \in \mathbb{Z}^d} \mathbb{G}_{\pm}^p (2Nz + y) \right\}^{\frac{1}{p}} \qquad \text{for any } y \in \mathbb{Z}^d.$$

By the triangle inequality we have $\widetilde{\mathbb{G}}_N \leq \widetilde{\mathbb{G}}_+ + \widetilde{\mathbb{G}}_-$. The induced operators $\widetilde{\mathfrak{A}}_{h,\pm} \colon L^2(A_N) \to L^2(A_N)$ are defined by

$$\widetilde{\mathfrak{A}}_{h,\pm} g(x) = \sqrt{e^{h(x)} - 1} \sum_{y \in A_N} \widetilde{\mathbb{G}}_{\pm}(x - y)\, \sqrt{e^{h(y)} - 1}\, g(y).$$

For the spectral radius of these operators we thus obtain

$$\|\widetilde{\mathfrak{A}}_{h,N}\| \leq \|\widetilde{\mathfrak{A}}_{h,+}\| + \|\widetilde{\mathfrak{A}}_{h,-}\|.$$

Suppose now that $h \colon A_N \to [0,\infty)$ is given and let $h_0 \colon \mathbb{Z}^d \to [0,\infty)$ its extension to the whole of $\mathbb{Z}^d$ defined by letting $h_0(x) = 0$ for $x \in \mathbb{Z}^d \setminus A_N$. We next show that

$$\|\widetilde{\mathfrak{A}}_{h,N}\| \leq \|\mathfrak{A}_{h_0}\| + \left(e^{\|h\|_q} - 1 \right) \left\{ \left\{ \sum_{|x| > M} \mathbb{G}^p(x) \right\}^{\frac{1}{p}} + 2 \left\{ \sum_{x \in \mathbb{Z}^d} \mathbb{G}^p(x) \right\}^{\frac{1}{p}} \left[\frac{\# E_N}{(2N)^d} \right]^{\frac{p-1}{p}} \right\}. \tag{13}$$

Using (13) we complete the proof by the following argument: For any $t > 0$ let

$$\varphi(t) := \inf \left\{ \|h\|_q \,:\, h \geq 0 \text{ with } \|\mathfrak{A}_h\| \geq t \right\}.$$

Note that, using that $\mathbb{G} \in L^p(\mathbb{Z}^d)$, by choosing first a large M and then an even larger N, we can make the expression in the curly bracket on the right hand side of (13) as small as we wish. Hence

$$\limsup_{N\to\infty} \inf \left\{ \|h\|_q \,:\, h \geq 0 \text{ with } \|\widetilde{\mathfrak{A}}_{h,N}\| \geq 1 \right\} \geq \varphi(1 - \varepsilon),$$

for any $\varepsilon > 0$. As $\frac{1}{1-\varepsilon}\left(e^\theta - 1 \right) \leq \exp\{\frac{\theta}{1-\varepsilon}\} - 1$ we obtain, from the definition of $\mathfrak{A}_h$ that

$$\left\| \mathfrak{A}_{\frac{h}{1-\varepsilon}} \right\| \geq \tfrac{1}{1-\varepsilon} \|\mathfrak{A}_h\|,$$

whence $\varphi(1 - \varepsilon) \geq (1 - \varepsilon)\,\varphi(1)$, so that the statement of Lemma 8 follows by letting $\varepsilon \downarrow 0$.

To prove (13) first fix $g \colon A_N \to [0,\infty)$ with $\|g\|_2 = 1$. For notational convenience we extend both g and h periodically to the whole lattice $\mathbb{Z}^d$. We claim that there exists $x_0 \in A_N$ such that

$$\sum_{x \in E_N} \left\{ g(x + x_0)\sqrt{e^{h(x+x_0)} - 1} \right\}^{\frac{2p}{2p-1}} \leq \left(e^{\|h\|_q} - 1 \right)^{\frac{p}{2p-1}} \frac{\# E_N}{(2N)^d}. \tag{14}$$

Indeed, this follows readily from

$$\sum_{\substack{x \in E_N \\ y \in A_N}} \left\{ g(x+y)\sqrt{e^{h(x+y)}-1} \right\}^{\frac{2p}{2p-1}} \leq \left\{ \sum_{\substack{x \in E_N \\ y \in A_N}} g^2(x+y) \right\}^{\frac{p}{2p-1}} \left\{ \sum_{\substack{x \in E_N \\ y \in A_N}} \left(e^{h(x+y)}-1 \right)^{\frac{p}{p-1}} \right\}^{\frac{p-1}{2p-1}}$$

$$\leq \left[\#E_N \right] \left\{ \sum_{y \in A_N} \left(e^{h(y)}-1 \right)^{\frac{p}{p-1}} \right\}^{\frac{p-1}{2p-1}} \leq \left[\#E_N \right] \left(e^{\|h\|_q}-1 \right)^{\frac{p}{2p-1}}.$$

We write $\bar{h}(x) = h(x+x_0)$ and $\bar{g}(x) = g(x+x_0)$. Then

$$\sum_{x,y \in A_N} g(x)\sqrt{e^{h(x)}-1}\, \widetilde{\mathbb{G}}_-(x-y)\sqrt{e^{h(y)}-1}\, g(y) = \sum_{x,y \in A_N} \bar{g}(x)\,\sqrt{e^{\bar{h}(x)}-1}\, \widetilde{\mathbb{G}}_-(x-y)\sqrt{e^{\bar{h}(y)}-1}\, \bar{g}(y)$$

$$\leq \sum_{x,y \in A_N \setminus E_N} \bar{g}(x)\,\sqrt{e^{\bar{h}(x)}-1}\, \widetilde{\mathbb{G}}_-(x-y)\sqrt{e^{\bar{h}(y)}-1}\, \bar{g}(y)$$

$$+ 2 \sum_{\substack{x \in E_N \\ y \in A_N}} \bar{g}(x)\,\sqrt{e^{\bar{h}(x)}-1}\, \widetilde{\mathbb{G}}_-(x-y)\sqrt{e^{\bar{h}(y)}-1}\, \bar{g}(y).$$

From the fact that $\widetilde{\mathbb{G}}_-(x-y) = \mathbb{G}_-(x-y)$ when $x, y \in A_N \setminus E_N$, we infer that

$$\sum_{x,y \in A_N \setminus E_N} \bar{g}(x)\,\sqrt{e^{\bar{h}(x)}-1}\, \widetilde{\mathbb{G}}_-(x-y)\sqrt{e^{\bar{h}(y)}-1}\, \bar{g}(y) \leq \|\mathfrak{A}_{h_0}\|.$$

Moreover, from Hölder's inequality,

$$\sum_{\substack{x \in E_N \\ y \in A_N}} \bar{g}(x)\,\sqrt{e^{\bar{h}(x)}-1}\, \widetilde{\mathbb{G}}_-(x-y)\sqrt{e^{\bar{h}(y)}-1}\, \bar{g}(y)$$

$$\leq \left\{ \sum_{x,y \in A_N} \widetilde{\mathbb{G}}_-^p(x-y) \left(\sqrt{\left(e^{\bar{h}(x)}-1 \right)\left(e^{\bar{h}(y)}-1 \right)}\, \bar{g}(x)\bar{g}(y) \right)^{\frac{p}{2p-1}} \right\}^{\frac{1}{p}}$$

$$\times \left\{ \sum_{\substack{x \in E_N \\ y \in A_N}} \left(\sqrt{\left(e^{\bar{h}(x)}-1 \right)\left(e^{\bar{h}(y)}-1 \right)}\, \bar{g}(x)\bar{g}(y) \right)^{\frac{2p}{2p-1}} \right\}^{\frac{p-1}{p}}.$$

To treat the *first factor*, note that, by periodicity,

$$\sum_{x,y \in A_N} \widetilde{\mathbb{G}}_-^p(x-y) \left(\sqrt{\left(e^{\bar{h}(x)}-1 \right)\left(e^{\bar{h}(y)}-1 \right)}\, \bar{g}(x)\bar{g}(y) \right)^{\frac{p}{2p-1}}$$

$$= \sum_{x \in A_N} \widetilde{\mathbb{G}}_-^p(x) \sum_{y \in A_N} \left(\sqrt{\left(e^{\bar{h}(x+y)}-1 \right)\left(e^{\bar{h}(y)}-1 \right)}\, \bar{g}(x+y)\bar{g}(y) \right)^{\frac{p}{2p-1}}.$$

Moreover, arguing as before using Hölder's inequality,

$$\sum_{y \in A_N} \left(\sqrt{\left(e^{\bar{h}(x+y)}-1 \right)\left(e^{\bar{h}(y)}-1 \right)}\, \bar{g}(x+y)\bar{g}(y) \right)^{\frac{p}{2p-1}}$$

$$\leq \left\{ \sum_{y \in A_N} \left(\bar{g}(x+y)\sqrt{e^{\bar{h}(x+y)}-1} \right)^{\frac{2p}{2p-1}} \right\}^{\frac{1}{2}} \left\{ \sum_{y \in A_N} \left(\bar{g}(y)\sqrt{e^{\bar{h}(y)}-1} \right)^{\frac{2p}{2p-1}} \right\}^{\frac{1}{2}}$$

$$\leq \left\{ \sum_{y \in A_N} g^2(y) \right\}^{\frac{p}{2p-1}} \left\{ \sum_{y \in A_N} \left(e^{h(y)}-1 \right)^{\frac{p}{p-1}} \right\}^{\frac{p-1}{2p-1}} \leq \left(e^{\|h\|_q}-1 \right)^{\frac{p}{2p-1}}.$$

For the *second factor* we obtain, using (14),

$$\sum_{\substack{x\in E_N \\ y\in A_N}} \left(\sqrt{\left(e^{\bar{h}(x)}-1\right)\left(e^{\bar{h}(y)}-1\right)}\,\bar{g}(x)\bar{g}(y)\right)^{\frac{2p}{2p-1}}$$

$$= \left\{\sum_{x\in E_N}\left(\bar{g}(x)\sqrt{e^{\bar{h}(x)}-1}\right)^{\frac{2p}{2p-1}}\right\}\left\{\sum_{y\in A_N}\left(\bar{g}(y)\sqrt{e^{\bar{h}(y)}-1}\right)^{\frac{2p}{2p-1}}\right\} \le \left(e^{\|h\|_q}-1\right)^{\frac{2p}{2p-1}}\frac{\#E_N}{(2N)^d}\,.$$

Summarizing, we have that

$$\|\widetilde{\mathfrak{A}}_{h,-}\| = \sup_{\|g\|_2=1}\sum_{x,y\in A_N} g(x)\,\sqrt{e^{h(x)}-1}\,\widetilde{\mathbb{G}}_-(x-y)\,\sqrt{e^{h(y)}-1}\,g(y)$$

$$\le \|\mathfrak{A}_{h_0}\| + 2\left(e^{\|h\|_q}-1\right)\left\{\sum_{x\in\mathbb{Z}^d}\mathbb{G}^p(x)\right\}^{\frac{1}{p}}\left[\frac{\#E_N}{(2N)^d}\right]^{\frac{p-1}{p}}\,.$$

In a similar fashion as above, or indeed as in Lemma 1, we also obtain that

$$\|\widetilde{\mathfrak{A}}_{h,+}\| \le \left\{\sum_{y\in A_N}\widetilde{\mathbb{G}}_+^p(y)\right\}^{\frac{1}{p}}\left(e^{\|h\|_q}-1\right) = \left\{\sum_{|x|>M}\mathbb{G}^p(x)\right\}^{\frac{1}{p}}\left(e^{\|h\|_q}-1\right)\,.$$

This proves (13) and hence completes the proof of the lemma.   □

3. Random walks in continuous time: Proof of Theorem 3

3.1 Tail behaviour of the intersection local time

In this section we prove that

$$\lim_{a\uparrow\infty}\frac{1}{a^{1/p}}\log\mathbb{P}\{\tilde{I}>a\} = -\frac{p}{\varrho}\,, \tag{15}$$

where ϱ is as in Remark 3. As this is essentially a simpler version of the proof of Theorem 2, we only give a sketch, further details can be filled in easily by copying the methods of our main result. The proof is carried out in *four steps*.

In the *first step* we reduce the problem to an analytic problem. By (6) it suffices to prove

$$\lim_{k\uparrow\infty}\frac{1}{k}\log\mathbb{E}\left[\frac{\tilde{I}^k}{(k!)^p}\right] = p\log\varrho\,.$$

Using the convention that $x_{\sigma(0)} := 0$, we get

$$\mathbb{E}\tilde{I}^k = \mathbb{E}\left[\sum_{x\in\mathbb{Z}^d}\prod_{j=1}^p\int_0^\infty \mathbb{1}\{X^{(j)}(t)=x\}\,dt\right]^k = \sum_{x_1,\ldots,x_k\in\mathbb{Z}^d}\left[\mathbb{E}\int_0^\infty dt_1\cdots\int_0^\infty dt_k\prod_{\ell=1}^k \mathbb{1}\{X(t_\ell)=x_\ell\}\right]^p$$

$$= \sum_{x_1,\ldots,x_k\in\mathbb{Z}^d}\left[\sum_{\sigma\in\mathfrak{S}_k}\int_0^\infty dt_1\int_{t_1}^\infty dt_2\cdots\int_{t_{k-1}}^\infty dt_k\,\mathbb{E}\prod_{\ell=1}^k \mathbb{1}\{X(t_\ell)=x_{\sigma(\ell)}\}\right]^p$$

$$= \sum_{x_1,\ldots,x_k\in\mathbb{Z}^d}\left[\sum_{\sigma\in\mathfrak{S}_k}\prod_{\ell=1}^k \mathsf{G}(x_{\sigma(\ell-1)}-x_{\sigma(\ell)})\right]^p,$$

and hence it suffices to prove that

$$\lim_{k\to\infty}\frac{1}{k}\log\frac{1}{(k!)^p}\sum_{x_1,\ldots,x_k\in\mathbb{Z}^d}\left[\sum_{\sigma\in\mathfrak{S}_k}\prod_{\ell=1}^k \mathsf{G}(x_{\sigma(\ell-1)}-x_{\sigma(\ell)})\right]^p = p\log\rho\,. \tag{16}$$

In the *second step* we provide the lower bound for (16). Let q be the conjugate of p, and use Hölder's inequality to obtain, for any nonnegative $h \in L^q(\mathbb{Z}^d)$ with $\|h\|_q = 1$,

$$\frac{1}{k!} \Bigg(\sum_{x_1,\dots,x_k \in \mathbb{Z}^d} \Big[\sum_{\sigma \in \mathfrak{S}_k} \prod_{\ell=1}^{k} \mathsf{G}(x_{\sigma(\ell-1)} - x_{\sigma(\ell)}) \Big]^p \Bigg)^{1/p} \geq \sum_{x_1,\dots,x_k \in \mathbb{Z}^d} \prod_{\ell=1}^{k} h(x_\ell)\, \mathsf{G}(x_\ell - x_{\ell-1}).$$

For any nonnegative $f \in L^{2p}(\mathbb{Z}^d)$ with $\|f\|_{2p} = 1$ we define $h := f^{2p/q}$ and $g := f^p$ and note that $\|g\|_2 = \|h\|_q = 1$ and $f^{2p-1} = \sqrt{hg}$. If we also fix a finite set $A \subset \mathbb{Z}^d$, we can find a constant $\delta > 0$ (depending on f and A) such that $h(x) \geq \delta g^2(x)$ for all $x \in \mathbb{Z}^d$, and $\mathsf{G}(x) \geq \delta$ for all $x \in A$. Then

$$\sum_{x_1,\dots,x_k} \prod_{\ell=1}^{k} h(x_\ell)\, \mathsf{G}(x_\ell - x_{\ell-1})$$

$$\geq \delta^2 \sum_{x_1,\dots,x_k} g(x_1) \mathbb{1}_A(x_1) \Big[\prod_{\ell=2}^{k} \sqrt{h(x_{\ell-1})}\, \mathsf{G}(x_\ell - x_{\ell-1}) \sqrt{h(x_\ell)} \Big] g(x_k) \mathbb{1}_A(x_k)$$

$$= \delta^2 \big\langle g\mathbb{1}_A, \mathfrak{B}_h^{k-1} g\mathbb{1}_A \big\rangle.$$

From the spectral theorem we infer that

$$\liminf_{k \uparrow \infty} \frac{1}{k} \log \big\langle g, \mathfrak{B}_h^{k-1} g \big\rangle \geq \ \log\langle g\mathbb{1}_A, \mathfrak{B}_h g\mathbb{1}_A \rangle + \log \|g\mathbb{1}_A\|_2$$

$$\xrightarrow{A \uparrow \mathbb{Z}^d} \log\langle f^{2p-1}, \mathfrak{G} f^{2p-1} \rangle,$$

and the lower bound in (16) follows as f was arbitrary from the positive unit ball of $L^{2p}(\mathbb{Z}^d)$.

In the *third step* we show that, for any finite set $A \subset \mathbb{Z}^d$,

$$\limsup_{k \to \infty} \frac{1}{k} \log \frac{1}{(k!)^p} \sum_{x_1,\dots,x_k \in A} \Big[\sum_{\sigma \in \mathfrak{S}_k} \prod_{\ell=1}^{k} G(x_{\sigma(\ell)} - x_{\sigma(\ell-1)}) \Big]^p \tag{17}$$

$$\leq p \log \sup \big\{ \langle f^{2p-1}, \mathfrak{G} f^{2p-1} \rangle \colon \text{ for } f \colon \mathbb{Z}^d \to [0,\infty) \text{ with } \operatorname{supp} h \subset A \text{ and } \|f\|_{2p} = 1 \big\},$$

where (for later reference) we replace Green's function wherever it occurs by an arbitrary symmetric kernel $G \colon \mathbb{Z}^d \to [0,\infty)$. The same tilting technique as in Lemma 7 gives, for a suitable polynomial P, $\mu = L_k^{\mathbf{x}}$ and $\phi(x) = \mu(x)^{1/q}$,

$$\sum_{\sigma \in \mathfrak{S}_k} \prod_{\ell=1}^{k} G(x_{\sigma(\ell)} - x_{\sigma(\ell-1)}) \leq P(k)\, k! \Big\{ \prod_{j=1}^{k} \mu(x_j)^{\frac{1}{p}} \Big\} \sum_{y_1,\dots,y_k \in A} \phi(y_1) \cdots \phi(y_k) \prod_{\ell=1}^{k} G(y_\ell - y_{\ell-1}).$$

Therefore we obtain

$$\frac{1}{(k!)^p} \sum_{x_1,\dots,x_k \in A} \Big[\sum_{\sigma \in \mathfrak{S}_k} \prod_{\ell=1}^{k} G(x_{\sigma(\ell)} - x_{\sigma(\ell-1)}) \Big]^p$$

$$= \sum_{x_1,\dots,x_k \in A} \exp\Big\{ k \sum_{z \in A} \mu(z) \log \mu(z) + o(k) \Big\} \Big[\sup_{\|\phi\|_q=1} \sum_{y_1,\dots,y_k \in A} \phi(y_1) \cdots \phi(y_k) \prod_{\ell=1}^{k} G(y_\ell - y_{\ell-1}) \Big]^p$$

$$= e^{o(k)} \Big[\sup_{\|\phi\|_q=1} \sum_{y_1,\dots,y_k \in A} \phi(y_1) \cdots \phi(y_k) \prod_{\ell=1}^{k} G(y_\ell - y_{\ell-1}) \Big]^p.$$

Let $g(x) := [\#A]^{-1/2} \mathbb{1}_A(x)$ so that $\|g\|_2 = 1$. Using that $\phi(x) \leq 1$ for all $x \in A$, we obtain

$$\sum_{y_1,\ldots,y_k \in A} \phi(y_1) \cdots \phi(y_k) \prod_{\ell=1}^{k} G(y_\ell - y_{\ell-1}) \leq [\#A] \left\langle g, \mathfrak{B}_\phi^{k-1} g \right\rangle \leq [\#A] \|\mathfrak{B}_\phi\|^{k-1},$$

from which the result readily follows.

In the *fourth step* we extend the result from finite sets to the full lattice $\mathbb{Z}^d$. Projection on a torus as in Section 2.6 gives

$$\sum_{x_1,\ldots,x_k \in \mathbb{Z}^d} \left[\sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{k} G(x_{\sigma(\ell)} - x_{\sigma(\ell-1)}) \right]^p \leq \sum_{y_1,\ldots,y_k \in A_N} \left[\sum_{\sigma \in \mathfrak{S}_k} \prod_{\ell=1}^{k} \widetilde{G}_N(y_{\sigma(\ell)} - y_{\sigma(\ell-1)}) \right]^p,$$

where

$$\widetilde{G}_N(x) := \left[\sum_{z \in \mathbb{Z}^d} G^p(2Nz + x) \right]^{1/p}.$$

Using (17) for this kernel gives

$$\limsup_{k \to \infty} \frac{1}{k} \log \frac{1}{(k!)^p} \sum_{x_1,\ldots,x_k \in \mathbb{Z}^d} \left[\sum_{\sigma \in \mathfrak{S}_m} \prod_{\ell=1}^{k} G(x_{\sigma(\ell)} - x_{\sigma(\ell-1)}) \right]^p \tag{18}$$
$$\leq p \log \sup \left\{ \langle f^{2p-1}, \mathfrak{G}_N f^{2p-1} \rangle : \text{ for } f \colon \mathbb{Z}^d \to [0,\infty) \text{ with } \operatorname{supp} f \subset A_N \text{ and } \|f\|_{2p} = 1 \right\},$$

where the operator $\mathfrak{G}_N$ stands for convolution with the kernel $\widetilde{G}_N$. Exactly as in the proof of (13) one shows that, for $0 < M < N$,

$$\sup \left\{ \langle f^{2p-1}, \mathfrak{G}_N f^{2p-1} \rangle : \text{ for } f \colon \mathbb{Z}^d \to [0,\infty) \text{ with } \operatorname{supp} f \subset A_N \text{ and } \|f\|_{2p} = 1 \right\}$$
$$\leq \sup \left\{ \langle f^{2p-1}, \mathfrak{G} f^{2p-1} \rangle : \text{ for } f \colon \mathbb{Z}^d \to [0,\infty) \text{ with } \|f\|_{2p} = 1 \right\}$$
$$+ \left[\sum_{|x|>M} G^p(x) \right]^{1/p} + 2 \left[\frac{\#E_N}{(2N)^d} \right]^{\frac{p-1}{p}} \left[\sum_{x \in \mathbb{Z}^d} G^p(x) \right]^{1/p},$$

where $E_N := \{x \in A_N \colon |x| > N - M\}$. The first term on the last line can be made arbitrarily small by choice of M. For any M the second term converges to zero as $N \uparrow \infty$. This shows that, as $N \uparrow \infty$, the variational problem on the right hand side of (18) converges to ϱ, thus completing the proof of (15).

4. Conclusion

We believe that the method of this paper opens up new avenues for the treatment of a wide range of intersection problems in supercritical dimensions, which are by no means limited to random walk. The major advantage of our approach over the established Donsker-Varadhan theory is its direct applicability to problems with an infinite time horizon. However, studying the upper tail behaviour of the intersection of the ranges requires additional ideas and is subject of ongoing research.
